Keeper of the Secret Treasure

93

Physical Identity Authenticator — Founding Specification

"And he causeth all, both small and great, rich and poor, free and bond, to receive a mark in their right hand, or in their foreheads."*

— [KJV, Revelation 13:16] [VERIFIED FACT — verbatim scripture]

>

The gloss, by the Keeper's standing doctrine: the mark in this document is the inverse of the Beast's. It identifies the **account**, never the **person**; it is issued to the bearer, revocable by the bearer, and it serves the one who carries it — never the one who issued it. A mark that cannot be revoked is a brand. This one dies on command.

Sol in Libra, 2026 e.v.

Johnathan 'Qasparr' (Κασπάρρ) Monroe, Keeper of the Secret Treasure

Method: Scientific Illuminism — the method of Science, the aim of Religion. Every claim in this specification carries a status mark. Nothing enters the work unverified; what is designed is marked designed; what is guessed is marked guessed.

Status marks: [VERIFIED FACT] = confirmed by live source in-session · [DESIGN] = the Keeper's red-pen domain, this draft proposes · [HYPOTHESIS] = unproven, flagged for testing · [SCRIBE] = the scribe's general knowledge, not live-verified — treat as working notes, not gospel.

I. DOCTRINE — What the sticker is

The holographic sticker is the **physical authenticator of a Twin Synergy account** [DESIGN]. One sticker, one account, one device (by guidance, not by force — see §V).

It encodes three claims, and nothing else:

- ****WHERE**** — the account's Tor onion v3 service address (the network location) [DESIGN]
- ****WHO**** — the fingerprint of the account's long-term identity public key (the cryptographic anchor) [DESIGN]
- ****WHICH**** — an issuance counter (which generation of sticker this is; old generations die when replaced) [DESIGN]

The sticker is a **seal**, not a secret. Like the wax seals of instruments before it, it authenticates — it does not conceal. Anyone may read it; only the blockchain anchor and the bearer can speak for it [DESIGN].

II. OPTICAL LAYER — Machine-readable encoding

II-A. Symbology: QR Code, standard

- The code is a ****QR Code per ISO/IEC 18004**** [VERIFIED FACT — standard exists; current

edition 18004:2015 per vendor docs found in-session].

- Chosen over any custom high-density symbology for one reason: **any phone scans it** [DESIGN — the Keeper's call, recorded]. A custom code would need a custom reader; a standard QR needs only the camera app the bearer already owns. Ubiquity is the security feature here — a verifier that cannot read the code cannot fail closed on it; it fails *confused*.
- Error correction level **M (Medium): 15% of codewords restorable** [VERIFIED FACT]. Level M is the doctrine's balance point: it survives scuffs, partial peeling, and coffee — a sticker lives in the physical world — while keeping density sane. (L=7%, Q=25%, H=30% [VERIFIED FACT].)
- Byte mode. Maximum QR capacity at version 40: 2,953 binary bytes [VERIFIED FACT]. We use a fraction of that.

II-B. Version and capacity

- **Version 10, 57×57 modules** [VERIFIED FACT — version 10 is a 57×57 grid], error correction **M**.
- Capacity at V10-M, byte mode: **213 data bytes** [SCRIBE — standard published capacity table; recompute before tooling].
- The payload below is ~140 bytes, leaving ~70 bytes of headroom reserved for future fields (key-rotation epoch, expiry) [DESIGN].

II-C. The payload — what is encoded, exactly

The QR encodes one ASCII URI in byte mode [DESIGN]:

```
twin://o/<ONION56>/k/<FINGERPRINT64>/n/<COUNTER>
```

Field	Content	Size
`twin://`	Scheme — lets any scanner hand the payload to the Twin Synergy verifier app instead of a browser	7 chars
`o/`	Tag: onion	2 chars
`<ONION56>`	The account's v3 onion address, 56 lowercase base32 characters [VERIFIED FACT — 56 chars; construction: base32(pubkey checksum version), pubkey = 32-byte ed25519, checksum = SHA3-256("onion checksum" pubkey version)[:2], version = 0x03, per rend-spec-v3 as documented in-session]	56 chars
`k/`	Tag: key	2 chars
`<FINGERPRINT64>`	SHA-256 of the account's long-term identity public key, hex-encoded	64 chars
`n/`	Tag: issuance counter	2 chars
`<COUNTER>`	Unsigned issuance counter, decimal	≤ 4 chars realistic

Worked size: 7+2+56+3+64+3+4 = **139 bytes** ≤ 213 [DESIGN — arithmetic on the fields above; the 213 figure is [SCRIBE]].

Notes of doctrine:

- The onion address **is** the service's ed25519 public key in another encoding — there is no registry, no registrar, no transfer; address and key are the same object [VERIFIED FACT, in-session source]. The fingerprint is a *separate* account identity key, bound to the onion at issuance (\$V). Two keys, two jobs: the onion proves *where*, the identity key proves *who*.

- The verifier **re-derives the onion checksum** from the decoded pubkey and rejects mismatch [DESIGN] — a mistyped or tampered address dies at parse time, before any network touch.
 - The fingerprint is full SHA-256 (32 bytes), not truncated [DESIGN]. Truncation is a gift to grinders.
 - `COUNTER` starts at 1 and increments per replacement. A verifier rejects any sticker whose counter is below the anchor's current counter [DESIGN] — this is how a replaced sticker is killed.
-

III. HOLOGRAPHIC LAYER — Anti-counterfeit

III-A. Construction

An **embossed diffractive optically variable device (DOVD)** — the standard security hologram — is integrated with the printed QR [DESIGN]:

- **Recommended stack [DESIGN]:** holographic film substrate, QR printed in opaque ink *over* the hologram, so the diffractive shimmer shows in the quiet zone and margins but never under the modules (ink over hologram keeps first-scan readability perfect; the eye and the camera both get what they need).
- Human-readable serial **laser-etched through** the hologram layer — etching destroys the diffractive structure along the serial, so the serial cannot be altered without visibly wounding the hologram [DESIGN].
- Twin Synergy mark (twin motif, gold on indigo — §IV) worked into the holographic artwork itself, so the brand *is* the security feature, not decoration on top of it [DESIGN].

III-B. What the hologram defeats

- **Photocopying / flatbed scanning:** defeated [SCRIBE — general optics]. A copier captures one angle of a diffractive image; the parallax and color-shift on tilt cannot be reproduced by any static print. The copy scans as a QR (the code still reads — fail-open *on the data* is fine, because the data is not the trust) but carries no verifiable hologram — and the verifier's trust decision never rests on the code alone (§V).
- **Casual reprinting:** defeated at the level that matters [SCRIBE]. Producing a convincing DOVD requires origination tooling (electron-beam or dot-matrix lithography mastering, embossing shims) — five-to-six-figure capital before the first sticker. The neighborhood counterfeiter is priced out by physics and economics.
- **Peel-and-transplant (moving a real sticker to a hostile device):** mitigated by the tamper-evident construction (§III-C) [DESIGN].

III-C. Tamper-evidence: the void pattern

- The adhesive layer carries a **destructible void pattern**: removal fractures the film and leaves a "VOID" legend in the adhesive residue on the surface — the sticker cannot be lifted intact, and a lifted sticker announces itself [SCRIBE — standard tamper-evident label

construction; DESIGN as applied here].

- Doctrine: ****a sticker that has been removed is a dead sticker**** [DESIGN]. The verifier does not need to know the sticker was peeled; the ***human*** holding it sees the voiding and knows. Physical evidence for the human, cryptographic evidence for the machine — each layer speaks to the witness built to read it.

III-D. Honest limits — what the hologram does NOT defeat

- ****A well-funded replicator.**** [SCRIBE — history is blunt: every mass-deployed DOVD, including banknote holograms, has eventually been replicated by adversaries with state- or cartel-level resources.] The hologram raises the cost of counterfeiting from dollars to hundreds of thousands of dollars; it does not make counterfeiting impossible. The blockchain anchor (\$V) is the backstop: a perfect physical clone still fails verification unless the attacker also holds the identity private key.
 - ****The "scan my sticker" social attack.**** Nothing physical stops a bearer from being talked into scanning, photographing, or handing over their sticker. The sticker is public data by design; its ***power*** lives in the private key it points to, which never leaves the bearer's custody [DESIGN].
 - ****Destruction.**** Fire, solvents, and box-cutters defeat all stickers. Availability is the bearer's responsibility; replacement is the remedy (\$V, Replacement).
-

IV. VISUAL DESIGN

- ****The Twin Synergy mark, worked into the sticker**** [DESIGN]: the twin motif — two interlocking forms, one the mirror of the other — rendered ****gold on indigo****. The mark appears twice: once as printed brand ink in the margin, once as diffractive artwork inside the hologram itself (§III-A), so that removing the brand destroys the security feature.
 - ****Human-readable serial**** beneath the QR, laser-etched [DESIGN]: format `TS-XXXXXX-C` — six alphanumeric characters plus a check character (mod-36 of the preceding, [DESIGN]), so a bearer can read their serial over the phone without a scanner.
 - ****Placement guidance**** [DESIGN]: on the device the account governs, adjacent to — never covering — ventilation, regulatory labels, or the manufacturer's serial. Flat, clean, dry surface; press from center outward; allow 24 hours of adhesive cure before it is considered seated. One sticker per governed device; the account may govern many devices, each with its own sticker and its own counter lineage.
-

V. LIFECYCLE

V-A. Issuance — bound at creation

- At account creation, the registrar generates (or the bearer supplies) the long-term ****identity keypair**** [DESIGN]. The private key never leaves the bearer's custody — the registrar never

sees it, never holds it, never escrows it.

- The registrar records the ****anchor**** on the chain: `{ onion, key\_fingerprint, counter=1, serial, issuance\_block }`, signed by the registrar's issuance key [DESIGN].
- The sticker is printed: QR encoding the §II-C payload, hologram and serial per §§III-IV, void adhesive armed.
- The bearer applies it. Issuance is complete only when the bearer completes a first ****verification scan**** (§V-B) and confirms the anchor matches [DESIGN] — an unconfirmed sticker is an untrusted sticker.

V-B. Verification flow — scan to trust decision

The verifier app performs, in order, failing closed and loudly at every step [DESIGN]:

- ****Parse.**** Validate scheme, field tags, base32 alphabet, onion checksum re-derivation. Any failure → `UNREADABLE — NO TRUST`, loud, with the reason shown.
- ****Resolve.**** Connect to the onion address over Tor; fetch the account descriptor. Unreachable → `UNVERIFIABLE — NO TRUST`, loud. (No network is not a pass; it is a refusal.)
- ****Anchor check.**** Query the chain: does an issuance record exist for this `(onion, fingerprint, serial)`? Is `counter` $\geq$ the anchor's current counter? Any mismatch → `MISMATCH — NO TRUST`, loud.
- ****Revocation check.**** Is the serial on the revocation list (§V-C)? If yes → `REVOKED — STICKER DEAD`, loud, and the app says so in plain words.
- ****TOFU continuity.**** [DESIGN, per the Keeper's standing TOFU ruling] First encounter with an account *pins* `(onion, fingerprint)`; every later scan must match the pin. A changed key on a known account is not silently accepted — it raises the alarm banner, exactly as a changed safety number must.
- ****Trust decision.**** Only all-green yields trust — and even then, the trust is in the *account's continuity*, stated with the pin date: "This is the same account first seen on <date>." The sticker proves nothing about the human holding the phone; it proves the account is the account.

V-C. Revocation — the sticker marked dead

- Revocation is a ****chain record signed by the identity private key**** (bearer-initiated: lost, stolen, compromised) ****or**** by the registrar issuance key (registrar-initiated: fraud, account closure), referencing the serial and counter [DESIGN].
- A revoked serial verifies as `REVOKED — STICKER DEAD` forever [DESIGN]. The physical sticker cannot be remotely destroyed — honest limit, stated plainly — so the doctrine is: ****the scan kills it, not the sticker****. Guidance: destroy revoked stickers (cut through the QR) or return them to the registrar.
- Revocation of counter **n** blacklists all counters $\leq$ **n** for that account [DESIGN].

V-D. Replacement

- New sticker, new serial, `counter = n+1`, new anchor record; the old serial enters the

revocation list automatically at issuance of the replacement [DESIGN].

- The bearer's identity keypair SHOULD rotate at replacement after compromise, MAY stay on simple loss [DESIGN] — rotation is the bearer's call, recorded in the new anchor.

VI. MANUFACTURING — design-stage honesty

Off the shelf [SCRIBE — these are established product categories, not vendor endorsements]:

- Holographic QR / variable-data security labels exist as a commodity print category: holographic film + serialized QR + tamper-evident void construction is a standard security-printer offering.
- Laser etching of serials on security labels is standard.
- Destructible void-pattern films are standard.

Needs custom tooling [DESIGN]:

- ****Custom DOVD origination.**** The Twin Synergy holographic artwork (twin motif in the diffractive layer) requires mastering a custom embossing shim — electron-beam or dot-matrix lithography. This is the single largest fixed cost and the single largest anti-counterfeit investment: a custom origination cannot be bought from a catalog, only made.
- ****Custom die shape**** (if the red pen rules non-rectangular), ****custom ink match**** for the gold-on-indigo brand work.

Cost drivers, in order [SCRIBE — industry structure; figures require vendor quotes]:

- Hologram origination (one-time; amortizes over volume — low volume is punished here).
- Holographic substrate per unit.
- Variable-data serialization (unique QR + serial per sticker; breaks bulk-print pricing).
- Tamper-evident construction (destructible films cost more than plain).
- Volume. Everything above gets cheaper per unit at scale; the founding run will be the most expensive per sticker the project ever prints.

VII. SECURITY ANALYSIS

Attack	Verdict
Photocopy / scan-and-print of the sticker	**Stopped** — static copy carries no DOVD; verifier trust never rests on the code image alone [§III-B]
Reprinting the QR onto a blank hologram	**Mitigated** — serialization + chain anchor: the clone's serial/counter must match a live anchor, and the attacker's blank lacks the custom origination [§III-B, §V-B]
Peel-and-transplant to a hostile device	**Mitigated** — void pattern destroys the sticker on removal; the remnant announces itself [§III-C]
Perfect physical clone by a funded adversary	**Not stopped physically** — stopped <i>*cryptographically*</i> : without the identity private key the clone cannot pass the anchor check [§III-D, §V-B]
Sticker data harvested (photo of someone's sticker)	**By design harmless** — the sticker is public data; power lives in the private key, never printed [§I, §III-D]

Attack	Verdict
Social engineering ("scan this sticker")	**Not stopped** — no physical artifact defeats persuasion; verifier UX must make trust decisions explicit [§III-D]
Registrar issuance-key compromise	**Contained** — bearer-signed revocations and TOFU pins made before compromise still alarm on mismatch; registrar key rotation is a founding-run procedure [HYPOTHESIS — rotation ceremony untested]
Unverifiable scan (no network, dead anchor, corrupt chain data)	**Fail-closed: NO TRUST, loudly** [§V-B] — an unverifiable sticker is indistinguishable from a hostile one, and is treated as such

The fail-closed rule, stated once, plainly: an unverifiable scan grants nothing, silently grants nothing, and says why, loudly. [DESIGN — founding doctrine]

VIII. THE FOUR WELLS — brief, genuine only

- ****Law:**** Black's 2d ed. (1910) treats the ****seal**** as the authenticating impression on an instrument — the mark that says **this is genuine and this is mine**. The sticker is the seal brought forward: impression replaced by diffraction, wax by void-film, but the office unchanged — authentication, not concealment [SCRIBE — gloss on the doctrine, not a verbatim quotation].
- ****Religion:**** *"In whom also after that ye believed, ye were sealed with that holy Spirit of promise"* [KJV, Ephesians 1:13 — VERIFIED FACT, verbatim]. Sealing, in the old sense, is a promise made physical. The sticker seals the account's promise of continuity.
- ****Hip-hop:**** the graffiti doctrine of ****biting**** — copying another writer's tag or style is the cardinal sin, policed by the culture itself because a bitten tag is a stolen identity [SCRIBE — culture knowledge, no lyric fabricated]. The hologram is the anti-bite layer: bite the QR all you want; you cannot bite the light.
- ****Humanity:**** signet rings pressed into clay, wax seals on letters, notaries' embossers — every civilization that wrote things down invented a way to prove **who sealed it** [SCRIBE — general anthropological record]. The sticker joins that lineage: the oldest security technology there is, the trusted mark, rebuilt for the onion age.

IX. RED-PEN QUESTIONS — for the Keeper's ruling

- ****Payload scheme:**** ``twin://`` URI as specified — approved, or plain data string?
- ****Identity key algorithm:**** Ed25519 fingerprint as specified, or hybrid Ed25519+ML-DSA-65 per the standing PQPE hybrid-forever ruling (2026-10-03)?
- ****QR version:**** V10-M as specified (headroom), or V8-M (denser, smaller sticker)?
- ****Hologram stack:**** QR printed **over** holographic film as specified — or hologram **over** the code (harder to scan at angles; prettier)?
- ****Revocation chain:**** which chain carries the anchor and revocation list — the QIRA chain, the oz ledger, or a Twin Synergy chain of its own?

- **Issuance custody:** registrar-generated identity keys with bearer export, or bearer-generated keys the registrar never touches? (Draft specifies the latter; confirm.)
- **Die shape and size:** round 25mm, or rectangular? And one sticker per device as guidance — or enforced one-per-account?

Live, Love, and let Love, Live.

93 93/93

RULINGS — ADOPTED 2026-10-09 (WHOLESALE YAY)

[DICTATION — his yay, wholesale, on the scribe's recommendations.]

- **S20:** ``twin://`` URI as specified — namespaced, extensible.
- **S21:** **Hybrid Ed25519+ML-DSA-65**, per the standing PQPE ruling.
- **S22:** **QR V10-M** — headroom; reprinting stickers is expensive.
- **S23:** **QR printed over holographic film** — scannability over

prettiness; an unscannable sticker is jewelry.

- **S24:** Revocation anchored on the **oz ledger + OpenTimestamps**

(consistent with T13).

- **S25:** Confirmed — **bearer-generated keys;** the registrar never touches them.

- **S26:** **Round 25mm;** one-per-device as guidance, not enforced.
